

Predicting European Football Results

By Ben Royles

Overview

Can European Football results be predicted with a high degree of accuracy? If possible, there is value in a monetary sense as well as social value. Football is the market leader in the Sports betting and Fantasy sports markets, both of which are predicted to almost double in value by 2030. Socially, a successful model would give fans a greater understanding of the game and the factors that help determine the final outcome.

Background

Football is typically a low scoring game, certainly when compared to the most popular North American sports. It is a game of fine margins, where the difference between winning, drawing or losing can come down to 1 or 2 key moments in the space of 90 minutes. This makes accurately predicting the outcome far more challenging and nuanced than in some other sports.

Dataset

The dataset was downloaded from <https://football-data.co.uk> . The initial format included team and league information, the final result and advanced statistics such as shots on target and fouls; a full glossary can be found in the appendix.

These statistics can explain the match with a good level of detail but obviously only exist once the match has occurred and would not be available to predict outcomes ahead of time

Cleaning and Preprocessing

Similar to most datasets, the first challenge was to tackle duplicated and missing data. Almost every column had missing data that was spread throughout the leagues and seasons which posed a number of problems. The most significant was that simply deleting the data could dramatically impact season running statistics, impacting averages and league positions. I discovered through extensive exploratory data analysis (EDA) that a large proportion of the missing data was in the form of partial duplicates. The data and teams involved matched but other columns were nulls. Once these were removed, the number of actual null values was significantly reduced.

| | id | Country | league | Div | Season | Date | HomeTeam | AwayTeam | Referee | FTHG | FTAG | FTR | HTHG | HTAG | HTR | HS | AS | HST | AST | HF | AF | HC | AC | HY | AY | HR | AR |
|-----------------------|----|---------|--------|-----|--------|------|----------|----------|---------|------|------|-----|------|------|-----|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|
| Original | 0 | 0 | 0 | 105 | 0 | 105 | 105 | 105 | 178290 | 107 | 107 | 107 | 165 | 165 | 165 | 145750 | 145750 | 145750 | 145750 | 147088 | 147088 | 145750 | 145750 | 145750 | 145749 | 145749 | 145750 |
| Duplicates Removed | 0 | 0 | 0 | 4 | 0 | 4 | 4 | 4 | 49228 | 6 | 6 | 6 | 64 | 64 | 64 | 16688 | 16688 | 16688 | 16688 | 18026 | 18026 | 16688 | 16688 | 16687 | 16687 | 16687 | 16688 |

I made the decision to remove the Referee column entirely as it was inconsistently populated to offer any value. Additionally, I don't believe that a specific referee has much impact on the outcome of the game. I was able to resolve the

remaining null values, with the exception of the advanced statistics, through selective removal, interpolation and manually searching for the missing information.

The main challenge with this dataset was to transform it from descriptive to predictive. Firstly, I duplicated the dataframe and adjusted the column names so each match had an entry from both team's perspectives which enabled me to calculate league statistics such as Points, League Position and Form. Advanced statistics were also transformed into season averages. After these calculations, I shifted all of the values so that they explain what position the team was in and what their averages were prior to the match beginning instead of after it.

| Points | Points before match | Match Week | League Position | Form | AverageFullTimeGoalsFor | AverageFullTimeGoalsAgainst | AverageHalfTimeGoalsFor | AverageHalfTimeGoalsAgainst | AverageShots | AverageShotsAgainst | AverageShotsOnTarget |
|--------|---------------------|------------|-----------------|----------|-------------------------|-----------------------------|-------------------------|-----------------------------|--------------|---------------------|----------------------|
| 3 | 12 | 8 | 4 | 0.533333 | 1.000000 | 0.571429 | 0.714286 | 0.000000 | 10.142857 | 9.000000 | 3.428571 |
| 0 | 51 | 30 | 4 | 0.266667 | 1.793103 | 1.068966 | 0.724138 | 0.551724 | 16.862069 | 8.758621 | 5.689655 |
| 1 | 24 | 23 | 12 | 0.533333 | 1.045455 | 1.409091 | 0.409091 | 0.636364 | 8.772727 | 8.272727 | 4.500000 |
| 1 | 0 | 4 | 10 | 0.000000 | 0.666667 | 2.333333 | 0.000000 | 1.333333 | 11.000000 | 12.333333 | 3.666667 |

| AverageShotsOnTargetAgainst | AverageFoulsCommitted | AverageFoulsAgainst | AverageCorners | AverageCornersAgainst | AverageYellowCards | AverageYellowCardsAgainst | AverageRedCards | AverageRedCardsAgainst |
|-----------------------------|-----------------------|---------------------|----------------|-----------------------|--------------------|---------------------------|-----------------|------------------------|
| 2.857143 | 13.142857 | 13.285714 | 4.000000 | 5.142857 | 1.857143 | 2.571429 | 0.142857 | 0.000000 |
| 3.413793 | 10.586207 | 10.862069 | 7.103448 | 3.931034 | 1.655172 | 1.620690 | 0.000000 | 0.034483 |
| 4.318182 | 13.545455 | 14.136364 | 4.863636 | 4.227273 | 1.909091 | 2.500000 | 0.045455 | 0.181818 |
| 6.000000 | 16.000000 | 10.666667 | 9.333333 | 4.666667 | 1.666667 | 2.000000 | 0.000000 | 0.000000 |

Once this was done, I transformed the data frame back into the original structure with the addition of each team's season running statistics prior to the match happening. The final data frame is similar to the one above, with each column appearing twice, once for the home team and once for the away team.

One thing that became clear from looking closely at the data is that home teams win more often than any other outcome. In order to gain more insight and hopefully provide more accurate predictions, I added stadium specific data to the data frame. This was scrapped from <https://opisthokonta.net/?p=619>

| | Team | FDCOUK | City | Stadium | Capacity | Latitude | Longitude | Country |
|-----|---------------------|--------------|--------------------|------------------|----------|-----------|-----------|---------|
| 121 | Paris Saint-Germain | Paris SG | Paris | Parc des Princes | 48712 | 48.841389 | 2.253056 | France |
| 141 | Charlton Athletic | Charlton | Greenwich | The Valley | 27111 | 51.486389 | 0.036389 | England |
| 31 | Hull City | Hull | Kingston upon Hull | KC Stadium | 25404 | 53.746111 | -0.367778 | England |
| 145 | Notts County F.C. | Notts County | Nottingham | Meadow Lane | 20211 | 52.942500 | -1.137222 | England |
| 163 | Brentford | Brentford | London | Griffin Park | 12763 | 51.488183 | -0.302639 | England |

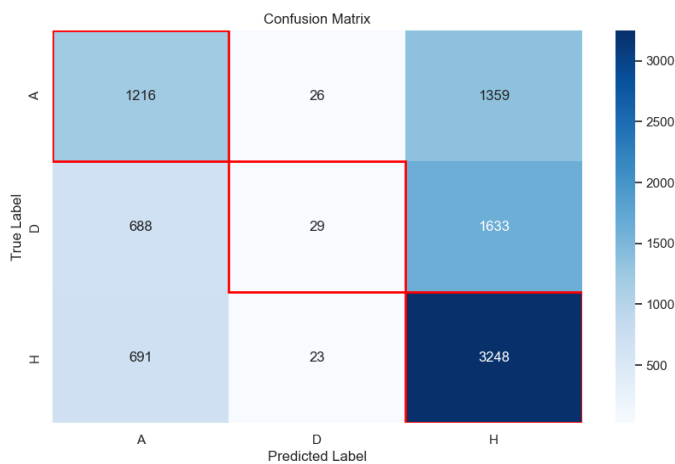

It included information about the geographic location in latitude and longitude, the team that plays there, and the capacity. Using this information, I calculated the distance the away team had to travel. I had hoped to find attendance data for every match but this was not possible, so for the purpose of this project, I have assumed that capacity and attendance are interchangeable and that each team utilizes the same proportion of their capacity for every game.

Insight and Results

I initially created models using only the data that had stadium information, which left me with around 21000 rows. After some experimentation, I concluded that it was better to remove the stadium information and create models using the larger dataset.

I ran some basic models to get a baseline and produced confusion matrices to highlight where they performed well and where they have weaknesses. The highlighted, red diagonals are the correct predictions.

Logistic regression 44.6%

Decision Tree 46.2%

The two models have similar overall accuracies, however, each model had its own distinct weaknesses. Logistic Regression overpredicts home wins, while the Decision tree overpredicts draws and predicts almost no away wins.

I proceeded to build and tune a variety of models in the hope of producing one that performs better. The hyper parameters were tuned using accuracy but I have included a number of evaluation metrics in the analysis as the importance of any particular one would be determined by the use case. I elected to keep the actual features I created and not undertake principal component analysis or any other dimensionality reduction as I want my models to be interpretable. As well as this, I experimented with balancing the classes in the training data using undersampling but this actually reduced the overall accuracy. Additionally, I experimented with feature forward selection, this too resulted in lower accuracy.

Logistic Regression

As a result of tuning hyperparameters I was able to score an accuracy of 50.3% on the test set which is quite a significant improvement. This was largely due to tuning the C parameter. Reducing the value of C and, therefore, increasing the strength of regularization, prevented the model from overfitting the training data. This resulted in better performance with the unseen test data. Looking at the top 5 coefficients for each class highlights the issue the model has predicting draws.

Away Win

| | Feature | Coefficient |
|----|---------------------------|-------------|
| 18 | AverageShots_away | 0.052970 |
| 22 | AverageShotsOnTarget_away | 0.044446 |
| 4 | Points before match_away | 0.043889 |
| 20 | AverageShotsAgainst_away | -0.039798 |
| 17 | AverageShots_home | -0.039591 |

Draw

| | Feature | Coefficient |
|-----|--------------------|-------------|
| 61 | Div_I2 | 0.018188 |
| 17 | AverageShots_home | -0.017622 |
| 8 | Form_away | 0.014339 |
| 124 | HomeCity_Iverness | 0.013199 |
| 76 | HomeCity_Barcelona | -0.012605 |

Home Win

| | Feature | Coefficient |
|----|------------------------------|-------------|
| 17 | AverageShots_home | 0.057213 |
| 18 | AverageShots_away | -0.044879 |
| 9 | AverageFullTimeGoalsFor_home | 0.044774 |
| 22 | AverageShotsOnTarget_away | -0.040871 |
| 21 | AverageShotsOnTarget_home | 0.040826 |

As you can see, away win and home win have much higher coefficients than draw, highlighting why the model predicts so few draws. Another interesting observation is that for away wins, the most important features are their own, whereas home win has a more even split of both their statistics and the opposing teams.

Decision Trees

I created a number of decision tree models, initially from tuning the hyper parameters and then advanced to random forest, gradient boost and XGBoost models. All of these showed some improvement from the original decision tree model with accuracies of between 48-50% on the test set. The XGBoost model scored the best with an accuracy of 50.5%

Binary Classification

Since most models struggled to classify draws, I experimented with using a binary logistic regression classifier for classes A and H. This actually caused a slight increase in accuracy with the test set. However, as the validation set scored lower, this may just be due to chance.

The diagram below illustrates the binary classification model, with colors representing actual outcomes (A, D, and H) in the testing set. The histograms depict the probabilities assigned by the model for each class based on input features. Probabilities above 0.5 are predicted as class H, and those below are class A. While there is some bimodality between classes A and H, significant overlap exists among all three classes. This overlap contributes to the models misclassifying many observations, particularly class D, which is likely to apply to all models.

I also manually set the decision boundary for A and H, as well as including a central region of the sigmoid curve for class D. While this did not improve overall accuracy, it did increase the precision for each class which may have some benefit, specifically in a betting context.

Findings and Conclusion

Football is a highly dynamic sport with numerous intertwined factors, including player performance, team dynamics, tactical strategies, and unpredictable chance events on the field. These complexities make predicting football outcomes a challenging task for any model.

Although there have been efforts to improve overall accuracy, the best approach depends on the model's intended use. Some improvements resulted in higher precision for specific classes, but predicting draws remained particularly challenging. The nature of draws as the "middle" value among the classes led to shared similarities with both class A and class H, contributing to the models' limitations.

Despite applying hyperparameter tuning and implementing gradient boosting, the models' overall accuracy only experienced a moderate increase from approximately 46% to 50.5%. Unfortunately, none of the models reached the target accuracy of 55%. However, I believe that achieving this goal is still possible with further feature engineering and potentially incorporating additional data, thereby empowering the models to make more accurate predictions. The complexity of football outcomes necessitates a continual quest for refined models that can better capture the nuances of this unpredictable sport.
